

INTERNSHIP REPORT

Introduction to Cloud Job Simulation

Submitted by	Naveen Kumar
Roll No.	CS-23411631
College	IILM University, Greater Noida
Course / Domain	B.Tech CSE (Cloud Computing)
Session	2023 – 2027
Year / Semester	4th Year, 7th Semester
Organisation	Datacom (via Forage)
Job Simulation	Introduction to Cloud

2026

1. Introduction

This report presents my experience in the Introduction to Cloud Job Simulation, completed through Forage with a workplace scenario based on Datacom and WCD Bank. The simulation gave me a practical introduction to the kind of activities a junior DevOps engineer may perform while supporting a cloud migration project.

The scenario centred on WCD Bank's move from on-premises data centres to cloud-based services. Datacom was involved as the subject-matter expert to support the project through stages such as implementation and migration.

My role in the simulation was positioned within the implementation phase. Instead of only studying cloud concepts, I worked through practical activities involving Azure, Microsoft Entra ID, GitHub and GitHub Actions.

2. About the Job Simulation

The simulation was designed to feel like an entry-level workplace experience. I was expected to follow technical instructions, complete assigned activities and ask for guidance when necessary. This made the learning more practical than simply reading about cloud and DevOps concepts.

Organisation	Datacom
Client scenario	WCD Bank
Role	Junior DevOps Engineer
Project phase	Implementation
Key tools	Azure, Microsoft Entra ID, Git, GitHub, GitHub Actions and YAML

3. Task 1 – Register an Application on the Cloud

The first task was mainly about preparing the working environment and understanding how an application can be registered in a cloud platform. The activity introduced me to the relationship between an application, its identity and the permissions it needs to access cloud resources.

Work completed

- Created or used a GitHub account for the development workflow.
- Installed and configured Visual Studio Code as the working environment.
- Created an Azure free account and explored the available cloud environment.
- Registered an application using Azure Active Directory / Microsoft Entra ID.
- Reviewed the basic concepts of permissions, client IDs and authentication.

What I learned

This task made cloud identity and access easier to understand in a practical way. I learned that an application needs a defined identity before it can interact with cloud resources, and that permissions help control what the application is allowed to access. I also gained a clearer understanding of why authentication is important in cloud-based systems.

Register An Application On The Cloud

Example Answer

Great work! Take a look at the example answer below to see how a professional would have attempted this task. Think about what you did well and how you can improve.

Figure 1: Evidence from the application-registration activity.

4. Task 2 – Create a GitHub Actions Workflow

The second task introduced GitHub as a practical DevOps tool. The activity started with source control and then moved towards automation. I created a repository, worked with Git locally, reviewed variables and created a GitHub Actions workflow using YAML.

Work completed

- Created a new GitHub repository.
- Installed and configured Git for local development.
- Cloned the repository to the local machine through the terminal.
- Reviewed the concept of variables used by GitHub Actions.
- Created the first GitHub Actions workflow using a YAML configuration file.

What I learned

The task helped me see how version control and automation can work together. A repository can be more than a place to store code; it can also act as the starting point for repeatable development processes. GitHub Actions allows these processes to be defined in a workflow file and executed automatically according to the workflow configuration.

This activity also gave me a first practical exposure to YAML-based automation and the broader DevOps idea of making software processes consistent and repeatable.

Figure 2: Evidence from the GitHub / DevOps setup activity.

5. Reflections and Learnings

The simulation gave me a more realistic view of cloud and DevOps work. The biggest difference from purely theoretical learning was having to follow a sequence of technical steps and understand how each step contributed to the overall task.

The Azure activity strengthened my understanding of application identity and access. Concepts such as permissions, client IDs and authentication became easier to relate to a real cloud environment after I worked through the registration process.

The GitHub activity built on that learning by showing how source control can lead into automation. Creating a repository, using Git and preparing a GitHub Actions workflow helped me understand the basic path from managing source code to automating development tasks.

I also learned an important professional habit: when working with unfamiliar tools, it is better to read the instructions carefully, test each step and ask for help rather than continue with an incorrect assumption. This made the simulation feel closer to a real team environment.

6. Conclusion

The Introduction to Cloud Job Simulation was a valuable first step in developing practical cloud and DevOps skills. The two main activities — registering an application in the cloud and creating a GitHub Actions workflow — helped me connect cloud identity, source control and automation.

By completing these activities, I became more familiar with Azure, Microsoft Entra ID, GitHub and GitHub Actions. More importantly, I developed a better understanding of how these tools can work together in a modern cloud project and gained confidence in following technical documentation, troubleshooting and learning new technologies.

Key Skills Developed

- Cloud fundamentals
- Azure and Microsoft Entra ID
- Git and GitHub
- GitHub Actions and YAML
- DevOps workflow awareness
- Technical problem solving and documentation
